1. Find the derivatives of the following functions. You may use any rule of differentiation. You don’t need to simplify your answer.

   a) $y = \frac{x}{(x^2 + 3)^{10}}$

   $\frac{dy}{dx} = \frac{(x^2 + 3)^{10} \cdot 1 - x \cdot 10(x^2 + 3)^9 \cdot 2x}{(x^2 + 3)^{20}}$

   [5]

b) $y = \tan(\sin(\sqrt{x}))$

   Here $y = f(g(x))$ where $f(x) = \tan x$ and $g(x) = \sin \sqrt{x}$.

   So $f'(x) = \sec^2 x$, and $f''(g(x)) = \sec^2 (\sin \sqrt{x})$.

   To find $g'(x)$, write $g(x) = h(\omega(x))$, where $h(x) = \sin x$ and $\omega(x) = \sqrt{x}$.

   So $h'(x) = \cos x$ and $\omega'(x) = \frac{1}{2\sqrt{x}}$. So

   $g'(x) = h'(\omega(x)) \cdot \omega'(x) = \cos (\sqrt{x}) \cdot \frac{1}{2\sqrt{x}}$.

   And

   $f'(g(x)) \cdot g'(x) = \sec^2 (\sin \sqrt{x}) \cdot \cos (\sqrt{x}) \cdot \frac{1}{2\sqrt{x}}$

   [5]

2. Find the equation of the tangent line to the graph of $xy^4 + 1 = 17$ at the point $(1, 2)$.

   $\frac{d}{dx} (xy^4 + 1) = \frac{d}{dx} (17)$

   [4]

   $\frac{d}{dx} (y^4) + 1 \cdot y^4 + 0 = 0$

   $x \cdot 4y^3 \frac{dy}{dx} + y^4 = 0$

   $4xy^3 \frac{dy}{dx} = -y^4$

   [1]

   $\frac{dy}{dx} = \frac{-y^4}{4xy^3}$

   [1]

   At $(x, y) = (1, 2)$, $\frac{dy}{dx} = \frac{-2}{4} = \frac{-1}{2}$.

   So the slope of the tangent line is $\frac{-1}{2}$, and

   the equation is $(y - 2) = \frac{-1}{2}(x - 1)$.

   [2]
